

# **Variations of the Solar Diameter and Spectral Irradiance: Measurements at total eclipses**

by:

**Serge Koutchmy**

with the collaboration of

**Cyril Bazin, Jean Mouette, Costantino Sigismondi, Jean-Yves Prado,  
Philippe Lamy and Patrick Rocher**

*Institut d'Astrophysique de Paris UMR 7095, CNRS and UPMC  
and*

*CNES, IMCCE, LAM, Sapienza Univ. of Rome*

During the last decades, considerable efforts have been devoted to the analysis of possible effects of the **irregular activity cycles** of the Sun through **solar forcing effects**

Topic connected to the question of the **anthropogenic origin of global warming** and to the influence of **volcanic activity**, with consequences for the **climate** and economic **life**.

Intriguing background (premises?):

**In ancient Egypt, the Sun was «excessively» proposed as a single divinity (pre-monotheism) leading to a catastrophic end of the reign of this famous Pharaoh ...**

**The “inhuman” Sun!**

**Akhénaton (Aménophis IV)  
v. 1350 B.C. (Cairo Museum) Aton**

Following the teaching of famous ancient philosophers like Plato, Aristotle and their followers, the **Man** and not the **Sun** has been put at the center of the World as reflected in modern religions (Judaism, Christianity, Islamisme etc.)

Aristotle (384 BC – 322 BC)  
([Greek](#): Ἀριστοτέλης, *Aristotélēs*)

Phenomena influencing our life could find their origin as a result of the **human activity**

*Unfortunately, the excessive belief in geo-centrism and creationism (model of the World in the middle age) leads to wrong conclusions about the real World.*

*Today:*

***Philosophy and Science became disconnected***

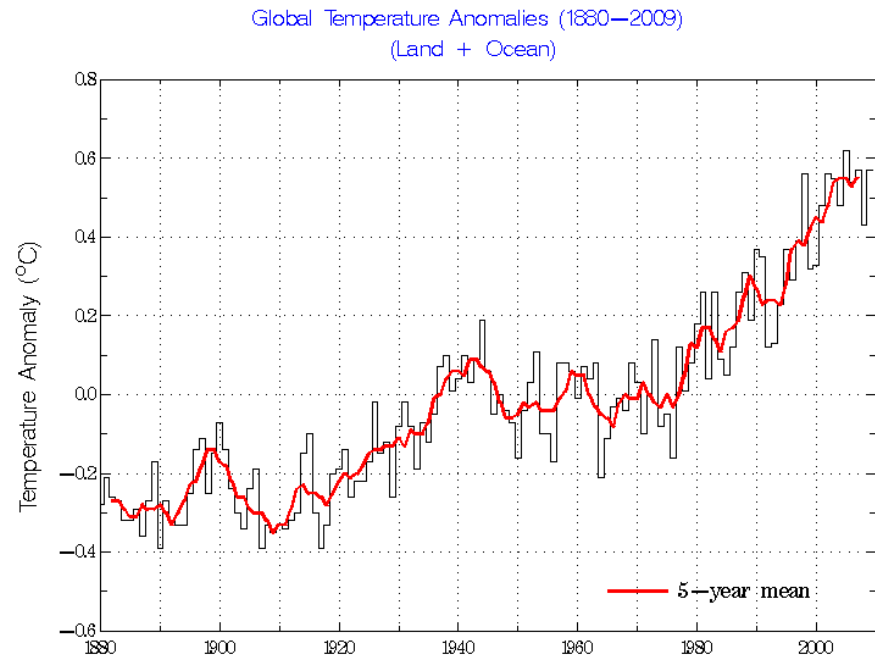

H. Schedel; Nuremberg (1493)

As regards **global warming**: It is now widely accepted  
(but not unanimously so)  
that a (dramatic?) global effect will “soon” result  
as a consequence of the well confirmed rising amount of CO<sub>2</sub>  
(and other components NO<sub>x</sub>, CH<sub>4</sub>..) in the Earth atmosphere,  
producing an increased **greenhouse effect**

***Reasonable but limited opinion  
(climato-sceptics exist)  
are however expressed***

Source: J.E. Hansen, R. Ruedy, M. Sato, and K. Lo  
NASA Goddard Institute for Space Studies

Conversely, there are data suggesting a possible solar effect:

Dendrochronological data- tree rings C14/ from J-M Malherbe, 2010 Lettre Acad Sc.

Fig. 3 : la concentration atmosphérique décennale en isotope  $^{14}\text{C}$  mesurée dans les anneaux de croissance des arbres (selon les données Intcal98, Quaternary Isotope Laboratory) donne une indication sur l'activité solaire ancienne

Historical records of extended periods of **global cooling**  
sometimes also called the “Little Ice Age”,  
(especially at the time of the **Maunder minimum**)  
and **warming episodes** like during the 11- 12th centuries  
⇒ Vikings in **Greenland** and **Iceland** in 800- 1200 (farming developed!),  
⇒ wine produced in England and competing with France (!), etc.,  
**suggest**

“solar activity could be responsible for important effects affecting our life”

**but: ice- core  $^{14}\text{C}$  and  $^{10}\text{Be}$  data suggest volcanic activity dominates**

The variations of the Total Solar Irradiance  $S$  can be analyzed assuming a simple model :

$$S = \sigma R_{\odot}^2 T_{\text{eff}}^4 / A^2$$

$A$  is the distance Sun-Earth (***an average over 1 Year is considered to remove the orbital modulation***) equal to the astronomical unit ( $A=\text{constant}$ ) while variations over the solar disk are neglected.

Variations can then be due to the changes of the solar radius  $R_{\odot}$  or/and of the effective temperature  $T_{\text{eff}}$  of the photosphere (possibly a consequence of global processes occurring deep inside the Sun):

$$\Delta S_{\odot} / S_{\odot} = 2 \Delta R_{\odot} / R_{\odot} + 4 \Delta T_{\text{eff}} / T_{\text{eff}}$$

Because the relative variations of the TSI  $S$  during a solar cycle is  $< 0.1 \%$ , the relative variation of the solar radius cannot be  $> 0.04$  and indeed, it is considerably smaller (possibly near 10 msec) due to the variations of the effective temperature  $T_{\text{eff}}$  of the quiet photosphere, *which, however, seems not correlated with the solar cycle and magnetic activity (Kitt Peak 35 Years long measurements using solar spectra (Livingston et al.)).*

# Total Solar Irradiance

Figure from C. Fröhlich

- TSI is lower this minimum than the previous two
- Unexpected change after a greatly disputed increase in the previous minimum
- Few mechanisms exist for magnetic changes in the basal solar luminosity

**To quantitatively translate solar magnetic modulation into irradiance variations, a clear mechanism-understanding is needed, or, better, evidence from solar “global” data are needed, including the solar radius variations**

**Measurements of the solar diameter variations have been performed for a long time (ex: A. Secchi book, 1872).**

# Several methods have been and/or are still used to measure the solar diameter:

- Specially designed **Heliometers**  
more than 100 Years old=> visual but still the best “canonic” value  
( $R=959''63$ ) !?;  
**a large (1''57) correction for “irradiation” effect is introduced;**
- Analysis of **planetary transits** (Mercury; Venus);
  - **Solar Astrolabes** working at almucantar at  
(long series; no correction for refraction; small aperture=> seeing);
- **Solar transit measurements** made with stationary G-B telescopes  
measuring at the same almucantar at;
- Analysis of **solar disk images made in Space**  
MDI of SoHO; HMI of SDO? and Rhesi guiding device signal  
dedicated **Picard mission**.
- Solar **Total Eclipse timing** of “contacts”.

A dedicated space mission was designed to avoid Earth Atmospheric effects (seeing)

## THE PICARD mission

Jean PICARD (1629 - 1692)

### Outline

PICARD launch and solar activity predictions

PICARD scientific objectives

PICARD measurements

PICARD Mission with its associated measurements

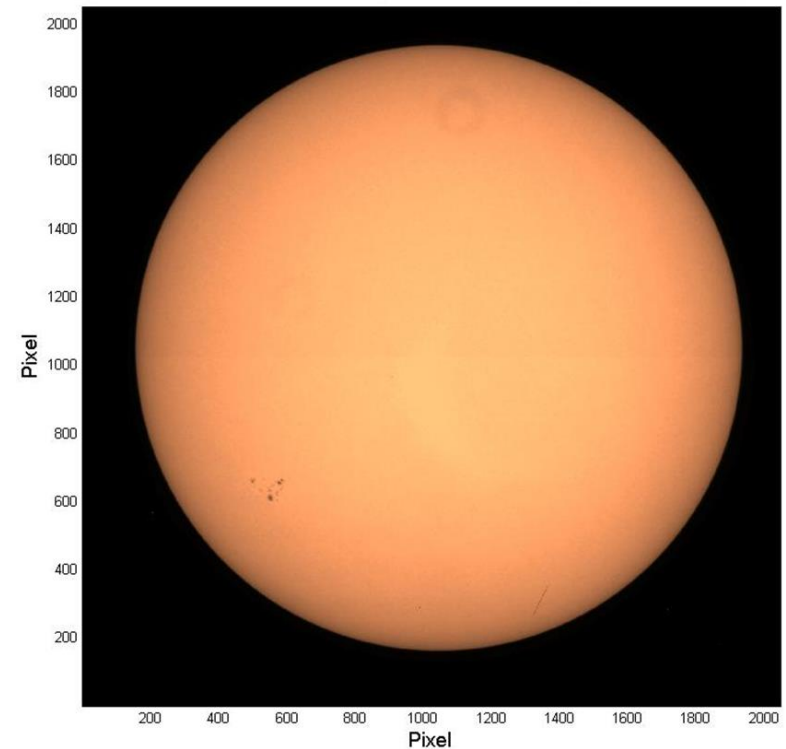

## “Picard mission” launched on June 15, 2010

*The SODISM instrument to measure the Solar Diameter using different filters (includes UV and KCall filters)*

1st light image on July 22, 2010.

After the commissioning phase (2010- 2011) orbital effects appeared, giving poor absolute values of the Solar diameter. Mission stopped in Apr.2013- 1 million images recorded.

***Failed to produce “direct” values due to orbital effects (Meftah et al, 2014) !!!!***

# The Solar Limb observed in the “pseudo-continuum” (broad band)

**More than 120 Years old visual  $\langle R_{sun} \rangle$  measurements of Auwers (1894) are still the best “canonic” value (959”63) used in Litterature!?!; But, a large (1”55) correction for “irradiation” effect was introduced. Irridiation effect is absent at time of Solar Total Eclipses.**

**Moreover, the true edge of the Sun Is not sharp and its spectrum could show variations**

**Figure 6:** (a) PSF for several values of Fried's parameter  $r_0$  according to the Kolmogorov turbulence model, through a telescope having the instrumental characteristics of the DORaySol instrument; (b) effect of atmospheric turbulence on the solar limb. From Djafer, et al. [5].

2008 ApJ

# Suggestions were made in 1980 that Solar Total Eclipses can produce critical measurements of the solar diameter

Early statements:

From *Science* 12 December 1980: Vol. 210. no. 4475, pp. 1243 - 1245

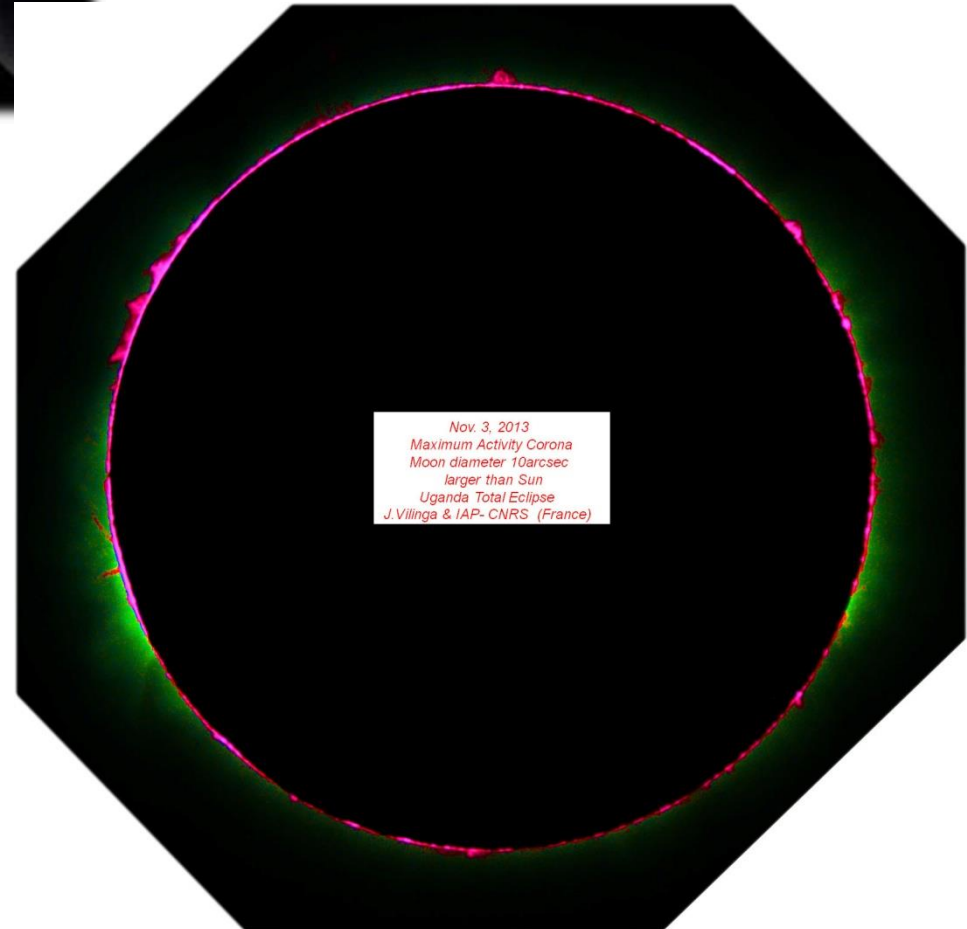

- **Observations of a Probable Change in the Solar Radius Between 1715 and 1979**
- **DAVID W. DUNHAM 1, SABATINO SOFIA 2, ALAN D. FIALA 3, DAVID HERALD 4, and PAUL M. MULLER 5**
- 1 International Occultation Timing Association, Post Office Box 488, Silver Spring, Maryland 20907  
2 Laboratory for Planetary Atmospheres, NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771  
3 U.S. Naval Observatory, Washington, D.C. 20390  
4 Post Office Box 254, Woden, ACT 2606 Australia  
5 Anglo-American Computers Ltd., Newcastle-on-Tyne, NE1 1LE England
- ***Solar eclipses were observed from locations near both edges of the paths of totality in England in 1715, in Australia in 1976, and in North America in 1979. Analysis of these observations shows that the solar radius has contracted by  $0.34 \pm 0.2$  arc second in 264 years.***

# Illustration of the method

*A magnified image from Jean Mouette to show the 3d contact during the last July 11, 2010 solar Total Eclipse (F660 mm; Canon 5D). :*  
***In white, the lowest layers;  
In pink, the chromosphere and prominences***

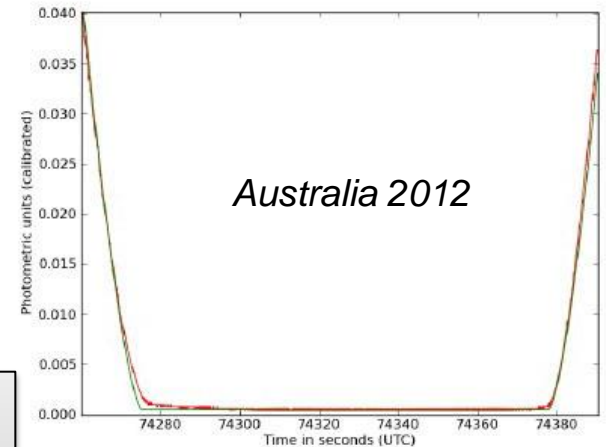

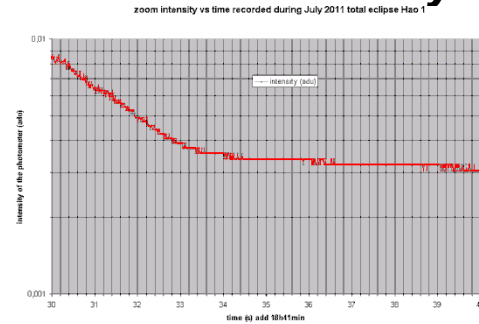

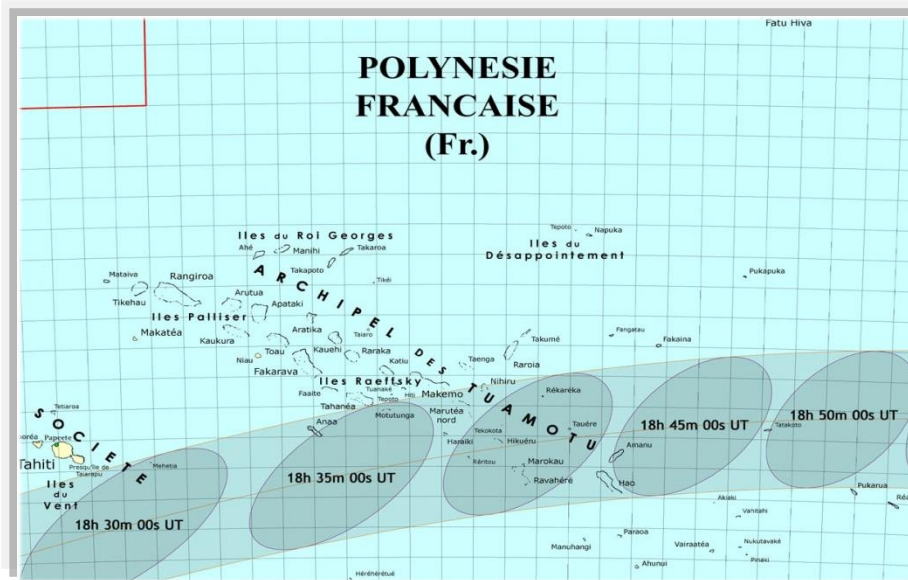

## Advantages of Eclipse Observations:

- Performed at ground => **economic**; small portable equipment;
  - Free of seeing effects because occultation occurs in Space;
- It is a differential method: **the lunar disk is used as a “cosmic” reference**  
(differential apparent motion of Sun and Moon  
magnified by  $>1/30$  compared to the diurnal motion)
- **Free of** spurious effects due to the **scattered (parasitic) light**  
from the disk like it is outside of total eclipses  
**unique method to correctly see the edge of the Sun!**

**Additional advantages** coming from the use of recent technologies:

- Precise timing and positioning using GPS devices;
- Fast CCD imaging and **spectrally resolved time series**;
- Finally: more precise lunar profiles are available  
from stellar occultations and from the Kaguya space mission.

**First results from single pixel photometric observations were obtained at the solar total eclipse of July 11, 2010 (and after, at the 2012 eclipse in Australia) Selected results were presented by J-P. Barriot Yesterday**

**Several specially designed by CNES  
Photometers and Sync-systems driven by GPS  
Several sites for performing the measurements  
at each total eclipse**  
***Designed for studying the long term solar diameter  
variations!***

**See also a Movie (extract)  
by Jean Mouette**

What about the **definition of the solar limb/edge** that is used?

*Campbel W.W.(1904)  
Eclipse spectrum  
obtained using a  
moving plate and  
a radial slit*

**Observations with good spectral resolution  
free of atmospheric effects are needed:  
slitless (flash) eclipse spectra**

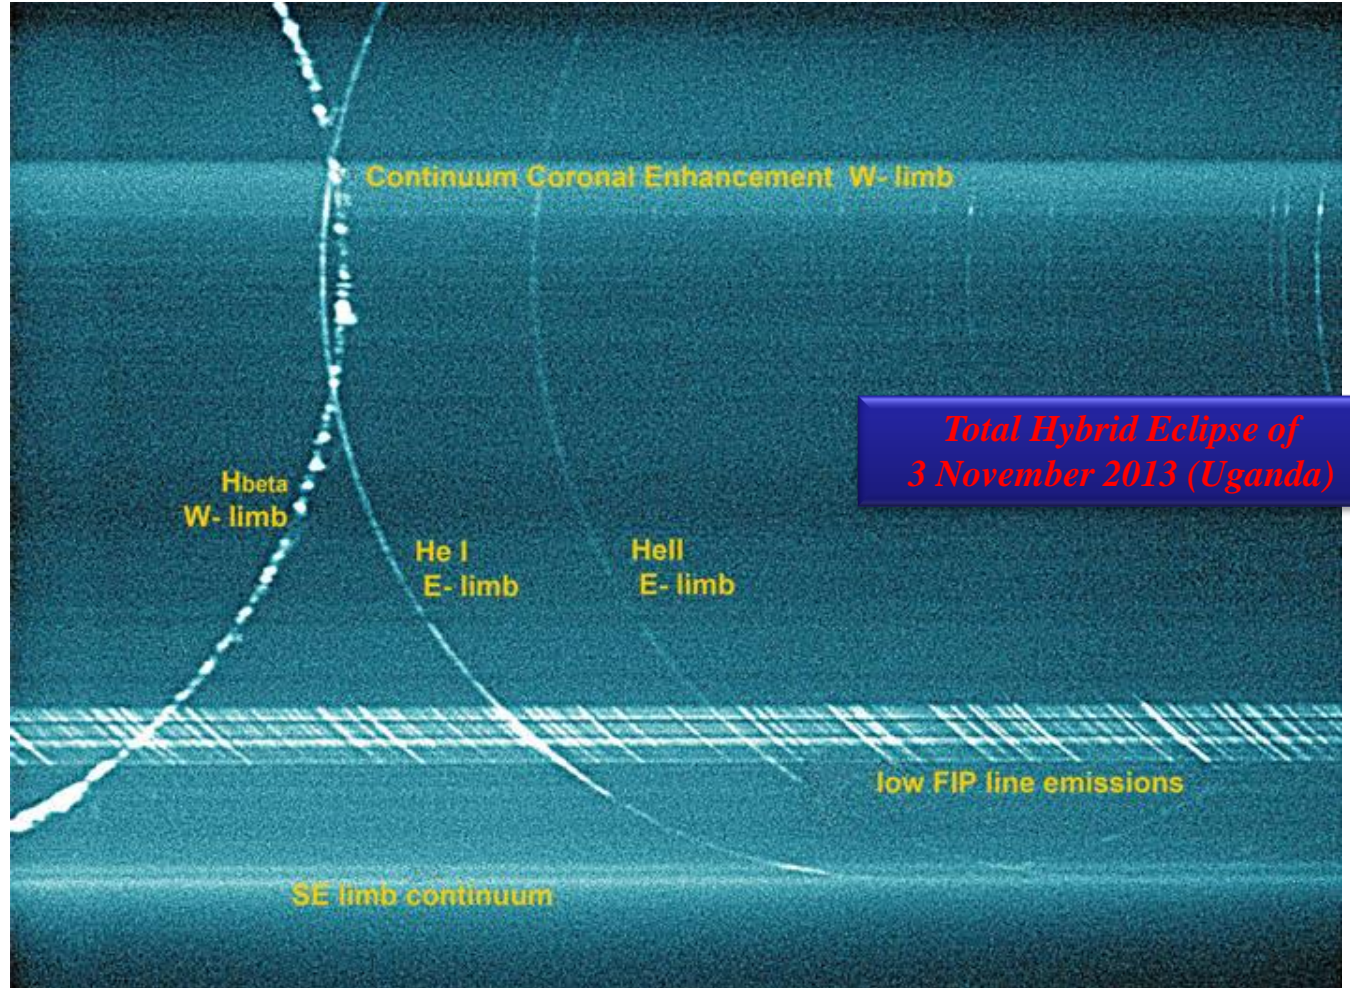

Flash spectra/SK/1200 l/mm F300mm Canon 40D; cadence 2 spectra/s; 2d contact

At a slow rate, 2010 eclipse in Hao- French Polynesia

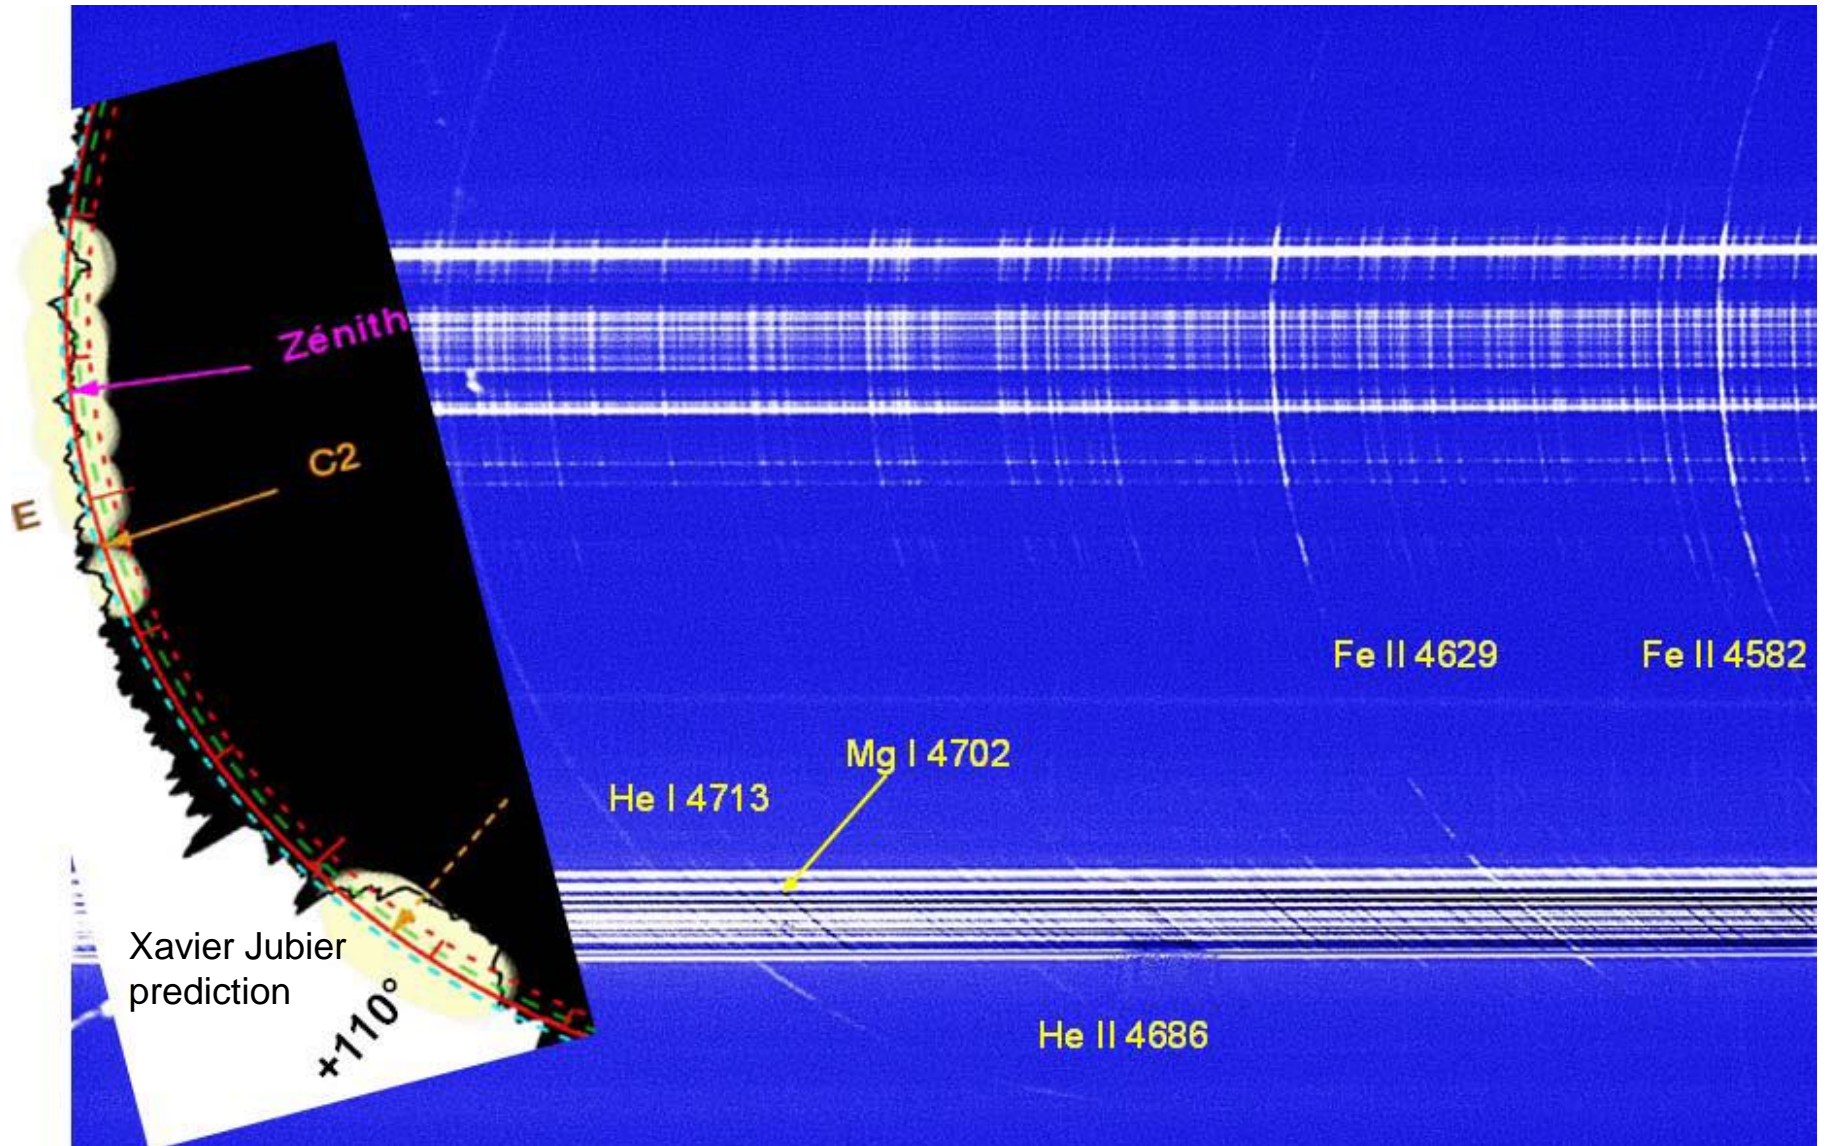

High Resolution CCD Eclipse Flash Spectrum  
near the 2d contact and the 460 to 490 nm region  
*to show **low excitation lines in emission,***  
***in addition to the faint chromospheric H $\beta$  HeI and HeII lines..***

Cadence is now  
15 sp/sec  
corresponding to #  
30 km on the sun  
provided the  
details of the lunar  
profile are taken  
into account

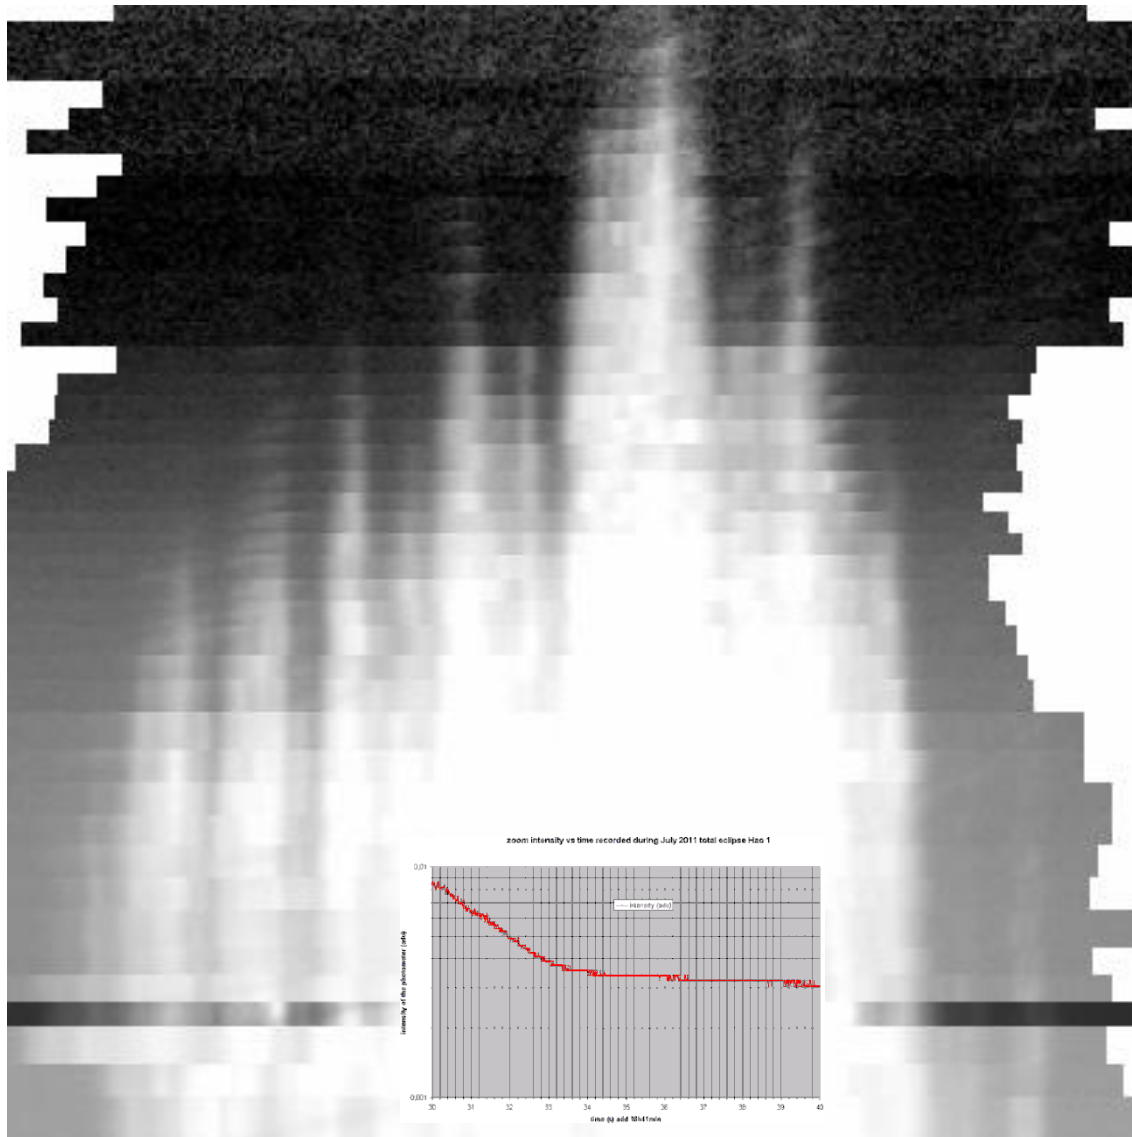

Spectra from the last 2013 eclipse observed in Uganda, just before

# Comparing with the limb profile from the classical Watts Lunar Atlas

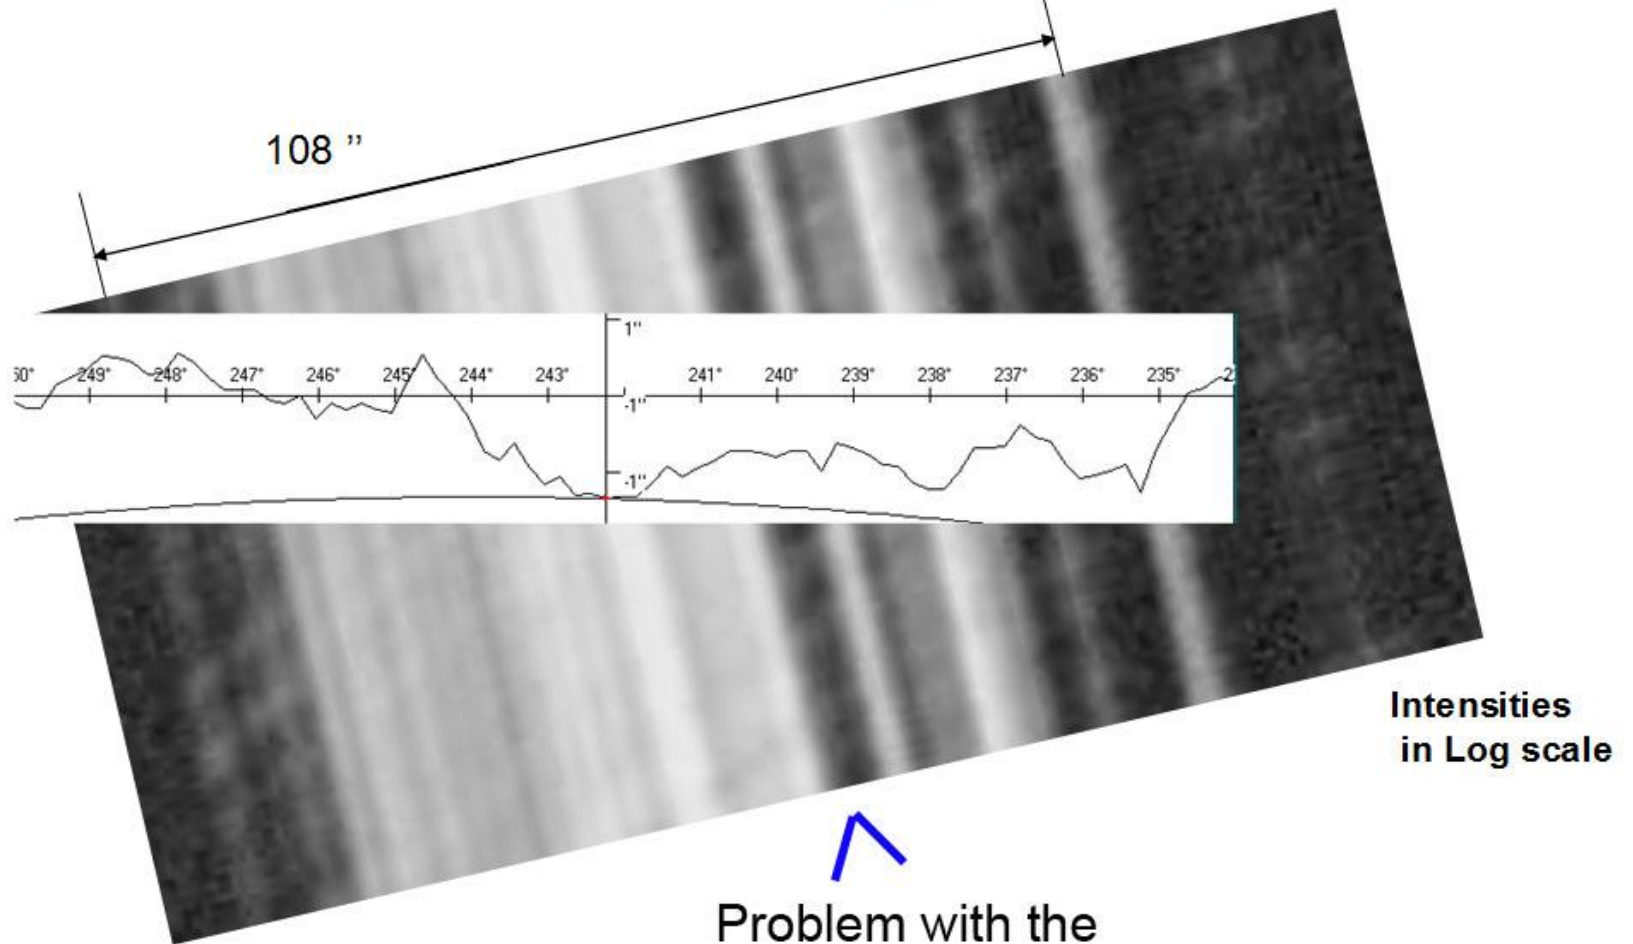

# At higher resolution:

Solar edge analysis

2009 eclipse

at 3rd contact – C3

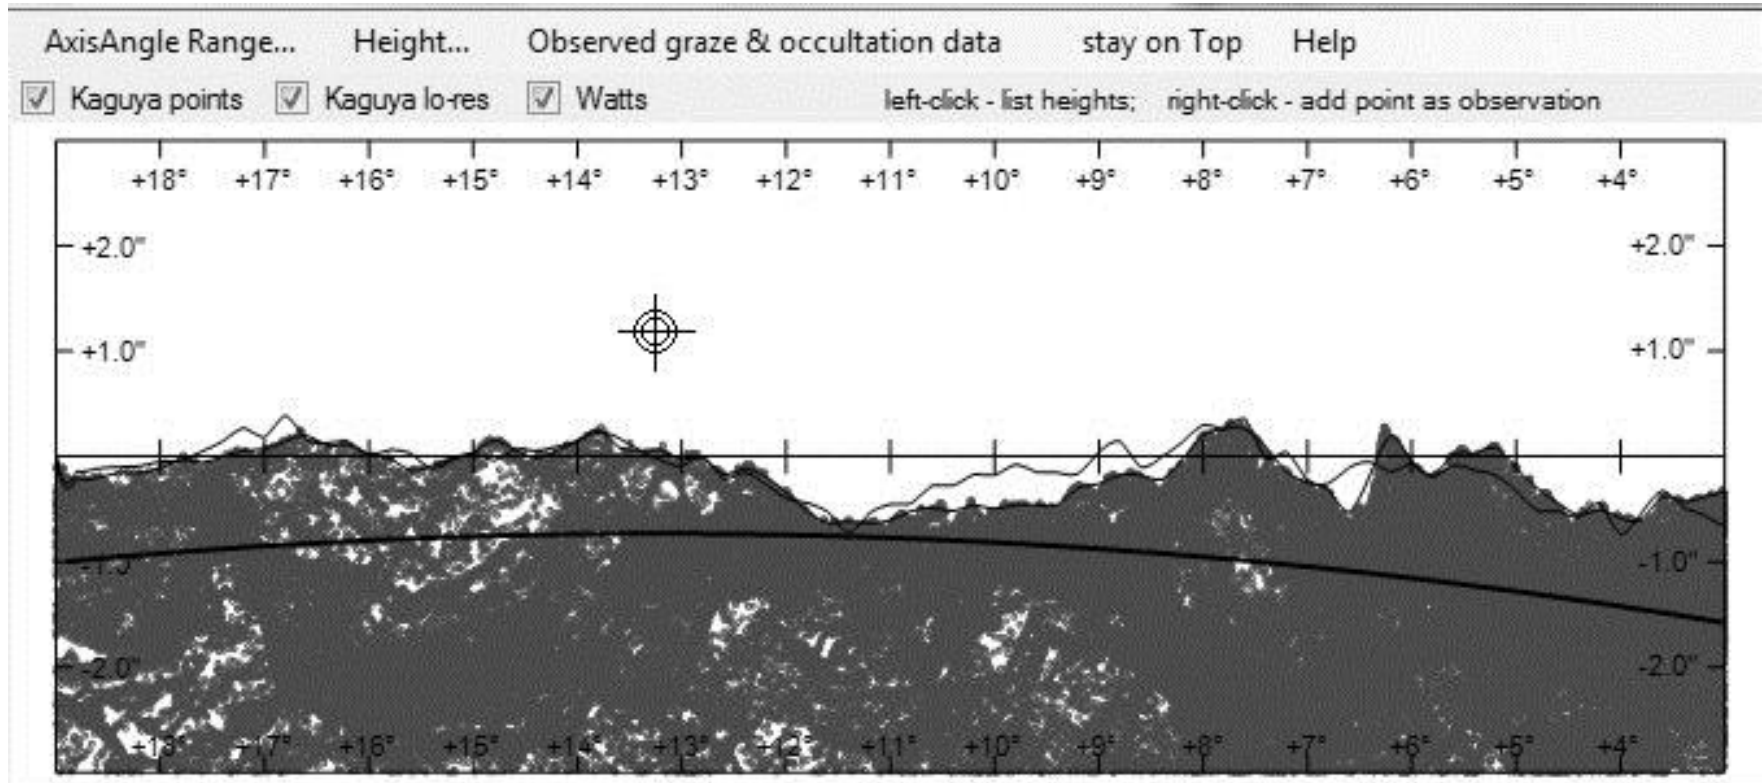

region of the He I line 471,3 nm

Problem with the  
predicted Watts  
Lunar profiles

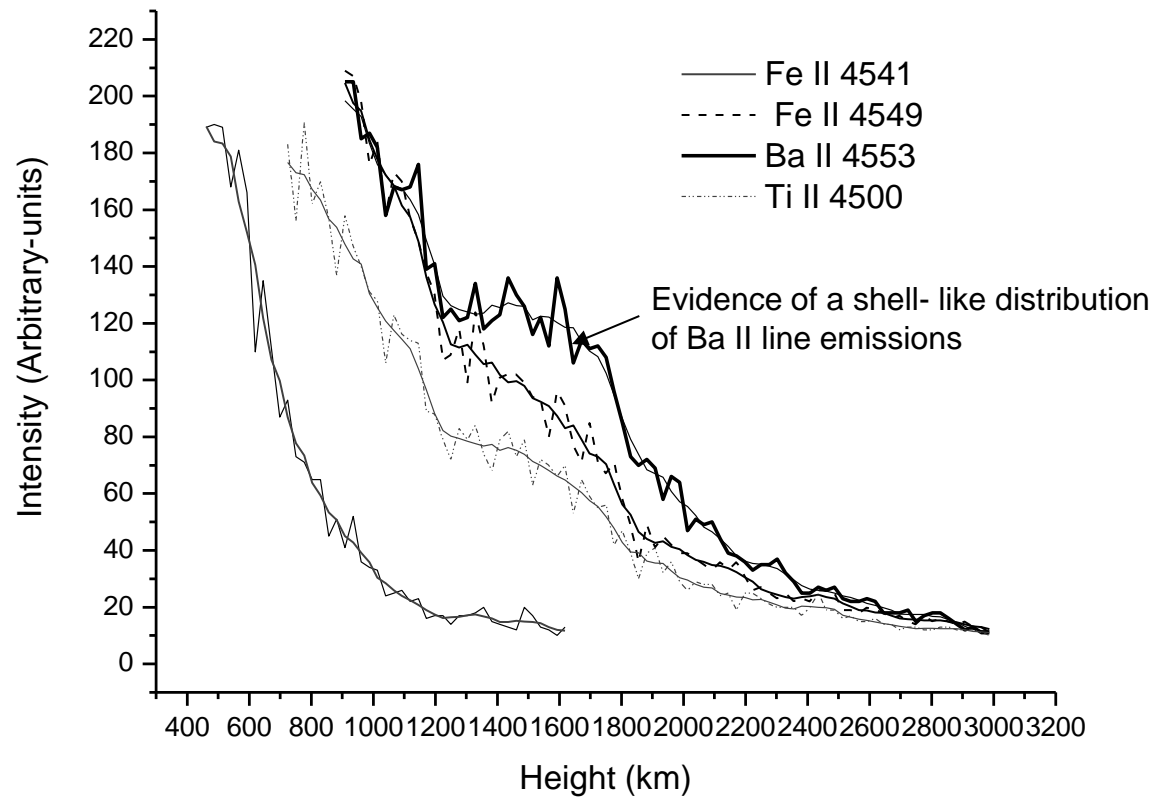

Improved lunar (3D) profiles should be used:...

Profiles from the Kaguya satellite altimetry (JAXA-preliminary), near C2

# Spectral lines at 2nd contact of July 22nd 2009 total solar eclipse in China

Intensity variations of the  
lines with height at 2d  
contact of the 22nd July  
2009 solar eclipse.

5 stacked flash spectra  
at the 2nd contact  
Frame rate of 15 images/s  
with a CCD Lumenera camera.  
Spectral lines around 454.1 nm

# Prospects:

- Solar diameter measurements using improved lunar profiles (Kagoya) and after averaging all the data from each eclipse, would permit a long term survey;
- New models of the upper layers of the solar atmosphere, immediately above the photosphere, should include magnetic effects !

*G-B Sac Peak H $\alpha$  image in negative*

*S-B SOT Hinode processed image in HCall*

# The position of the limb depends of the parameters of the Solar Atmosphere

# In conclusion

- Eclipse contact evaluations using quantitative measurements (photometers + GPS) give excellent results but total eclipses are rare events: Good for analyzing **long term solar diameter variations!**
- Besides the **emission lines** of the solar edge, true weak continuum is difficult to measure and flash spectra are needed;
- **Intensity variations of faint emission lines superposed on the true continuum, during the last and the first Baily's beads (near the 0.5 to 1 Mm heights) must be discussed to interpret historical (visual) and broad band contemporary results;**
- A new **Solar edge** definition is needed: role of the faint singly ionized emission lines seen at the limb ? Interpretation in term of SSI is better.
- The **solar global magnetism** clearly influence the details of the layers at the limb.
